## Comparison of SVM implementations (Support Vector Machine) on large dataset.

Support vector machines (SVM) are a set of related supervised learning methods used for classification and regression. Viewing input data as two sets of vectors in an  $n$ -dimensional space, an SVM will **construct a separating hyperplane in that space, one which maximizes the margin** between the two data sets. The original optimal hyperplane algorithm proposed by Vladimir Vapnik in 1963 was a linear classifier. However, in 1992, Bernhard Boser, Isabelle Guyon and Vapnik suggested **a way to create non-linear classifiers by applying the kernel trick** (originally proposed by Aizerman et al.) to maximum-margin hyperplanes. The resulting algorithm is formally similar, except that every dot product is replaced by a non-linear kernel function. This allows the algorithm to fit the maximum-margin hyperplane in the transformed feature space. The transformation may be non-linear and the transformed space high dimensional; thus though the classifier is a hyperplane in the high-dimensional feature space it may be non-linear in the original input space ([http://en.wikipedia.org/wiki/Support\\_vector\\_machine](http://en.wikipedia.org/wiki/Support_vector_machine)).

Our aim is to compare various free implementation of SVM, in terms of accuracy and computation time. Indeed, because the heuristic nature of the algorithm, we can obtain different results according to the used tools on the same dataset. In fact, in the publications describing the performance of SVM, we should not only specify the parameters of the algorithm but also indicate what is the tool used. This latter can influence the results.

SVM is very effective in domains with very high number of predictive variables, when the ratio between the number of variables and the number of observations is unfavorable. In the other hand, when the number of instances is high compared to the number of descriptors, it is not really attractive in comparison to well known approaches such as logistic regression or linear discriminant analysis. We are in a domain which is particularly favorable to SVM in this tutorial. We want to discriminate two families of proteins from their description with amino acids. We use sequence of 4 characters (4-grams) as descriptors. Thus, we can have a large number of descriptors (31,809) in comparison to the number of examples (135 instances).

From a certain point of view, we deal with a large dataset here. But unlike the standard situation we have a high number of variables. It is interesting to study the behavior of the tools in this situation. Most of the tools load the whole dataset into the main memory. The memory ability of the computer is then the main bottleneck. The feasibility of the computation relies of the utilization of the memory, in addition to the dataset, during the learning process.

We use the OS information for measuring the memory occupation. About the calculations time, we use the information supplied by the tools or, if it is not available, we use a chronograph. This is not very accurate, but this is the order of magnitude that is most important.

We use a 5 fold cross validation for the error rate estimation. We cannot control the subdivision according the tools. But, the results remain comparable. These are the large deviations that are interesting to analyze.

We use the following tools:

Software	Version	URL
ORANGE	1.ob2	<a href="http://www.aialab.si/orange/">http://www.aialab.si/orange/</a>
RAPIDMINER	Community Edition 4.2	<a href="http://rapid-i.com/">http://rapid-i.com/</a>
TANAGRA	1.4.27	<a href="http://eric.univ-lyon2.fr/~ricco/tanagra/">http://eric.univ-lyon2.fr/~ricco/tanagra/</a>
WEKA	3.5.6	<a href="http://www.cs.waikato.ac.nz/ml/weka/">http://www.cs.waikato.ac.nz/ml/weka/</a>

Other tools have been tested. They failed during the data loading or during the learning process. We will list them below. It is possible that these failures are due to misuse or improper. This cannot be excluded. The data file of this tutorial is available online. Anyone can carry out the same experiment and probably find the right settings.

This document fills out the tutorials dedicated to the comparison of tools<sup>1</sup>.

## 2 Dataset

We deal with a protein classification problem. We want to discriminate two families of proteins from their description, a sequence of 4 amino acids. Because, there are 20 kinds of amino acids, the theoretical number of descriptors is  $20^4 = 160.000$ . Many of them are not present in the dataset. We have "only" 31809 descriptors. There are 135 instances.

The WIDE\_PROTEIN\_CLASSIFICATION.TXT data file is in a compressed archive<sup>2</sup>.

**Note:** Some OS use "," as decimal separator. In this case, use a text editor to replace "." by "," before launching Tanagra.

## 3 Experiments results

### 3.1 ORANGE

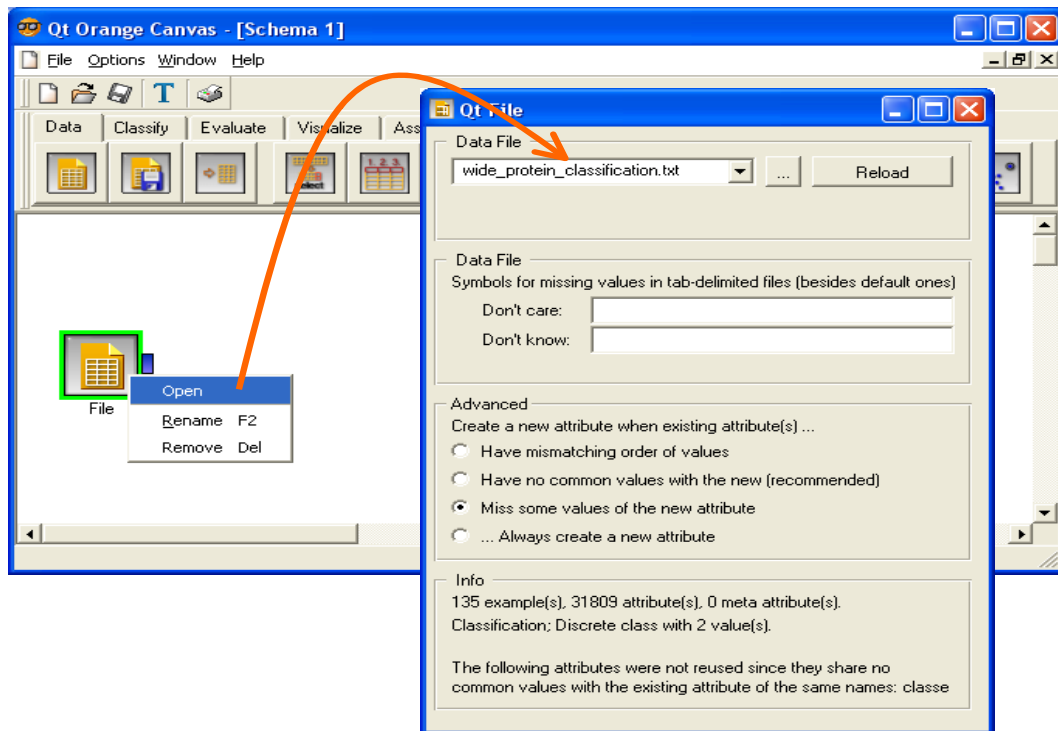

When we start ORANGE, PYTHON is automatically launched. The memory occupation is 25 MB.

In a new schema, we add the FILE component. We click on the OPEN menu in order to select the data file. As soon as the file is selected, the dataset is loaded. The computation time is 95 seconds. The memory occupation becomes 118 MB.

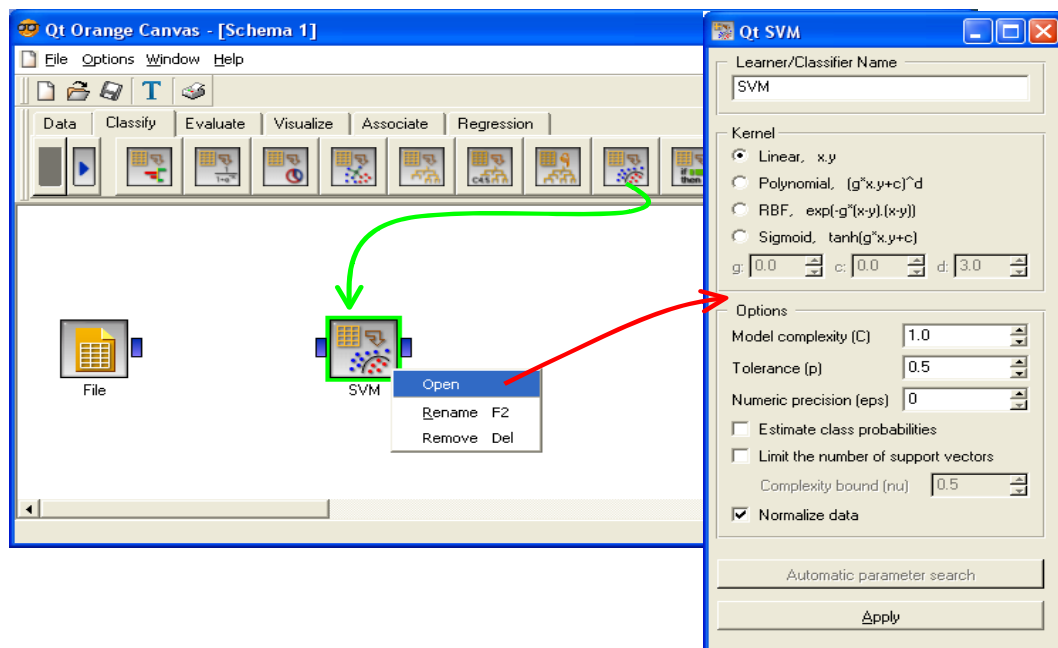

---

<sup>1</sup> <http://data-mining-tutorials.blogspot.com/search/label/Software%20Comparison>

<sup>2</sup> [http://eric.univ-lyon2.fr/~ricco/tanagra/fichiers/wide\\_protein\\_classification.zip](http://eric.univ-lyon2.fr/~ricco/tanagra/fichiers/wide_protein_classification.zip)

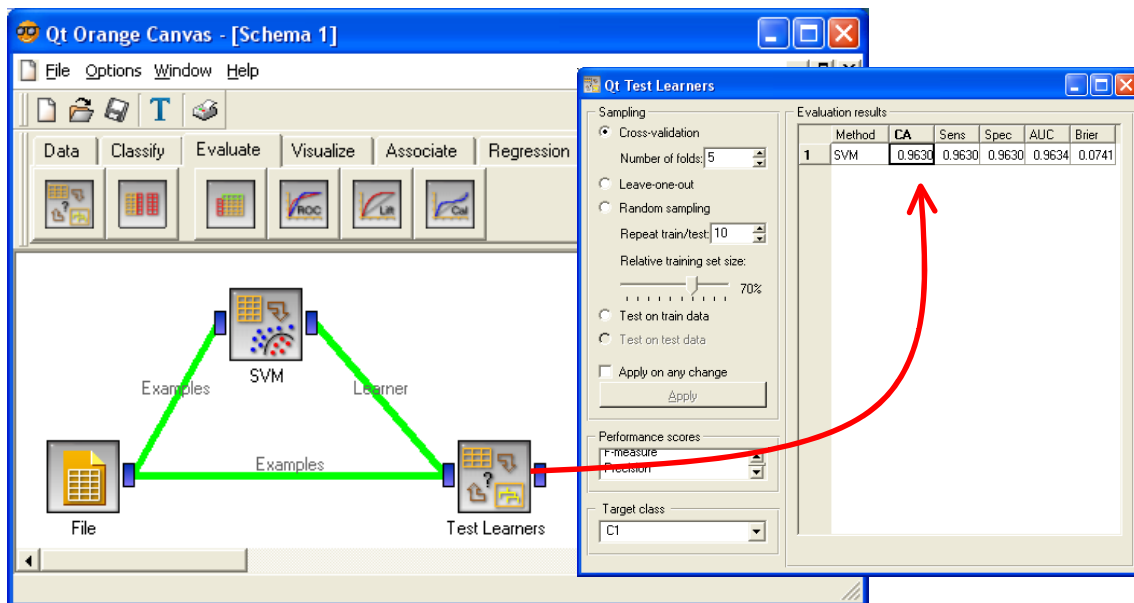

We add the SVM component (CLASSIFY tab) into the schema. We activate the OPEN menu to set the appropriate parameters. We ask a linear SVM, we set the MODEL COMPLEXITY to 1.0. We will use the same settings for the other tools below.

Then we set the link between FILE and SVM. The processing is automatically launched. The calculation time is 690 seconds (~ 11 minutes).

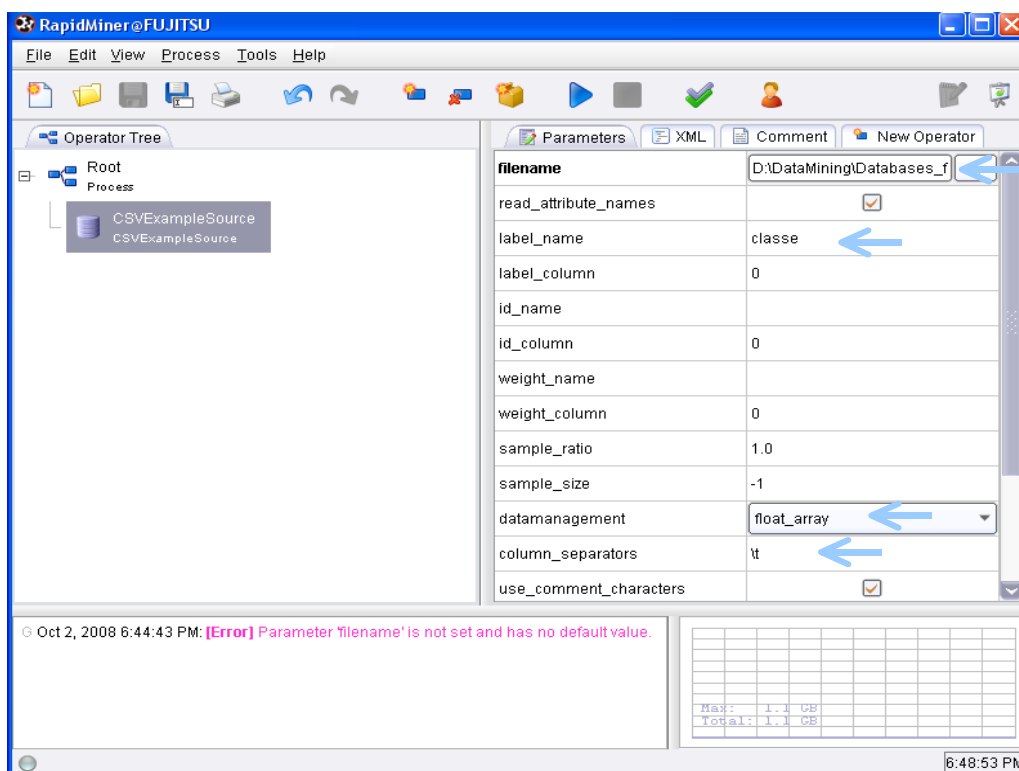

In order to obtain the (5-fold) cross validation error rate estimation, we add the TEST LEARNERS component into the schema. Here also, it is more suitable to specify the settings before establishing the link between the components. The error rate is 4%.

The peak of memory occupation during the whole process is 406 MB.

### 3.2 RAPIDMINER

The Java Virtual Machine is automatically started when we launch RAPIDMINER. The memory occupation is 124 MB. After we create a new diagram, we insert the CSVEXAMPLESOURCE. The settings must be specified with caution: FILENAME states the file name; LABEL\_NAME states the class attribute; we use a real with single precision for the data storage (DATAMANAGEMENT); the COLUMN\_SEPARATORS is tabulation. The processing time is 5 seconds. The memory occupation becomes 210 MB.

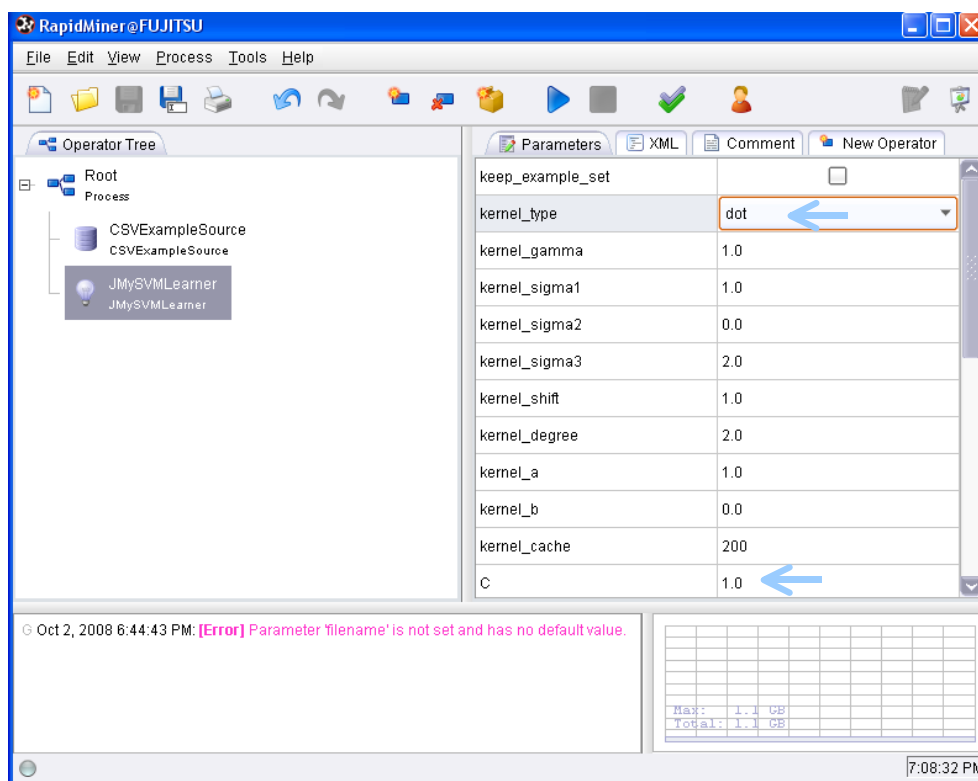

RAPIDMINER supplies two components for SVM implementation. We test them in turns.

### 3.2.1 RAPIDMINER – JMYSVMLEARNER

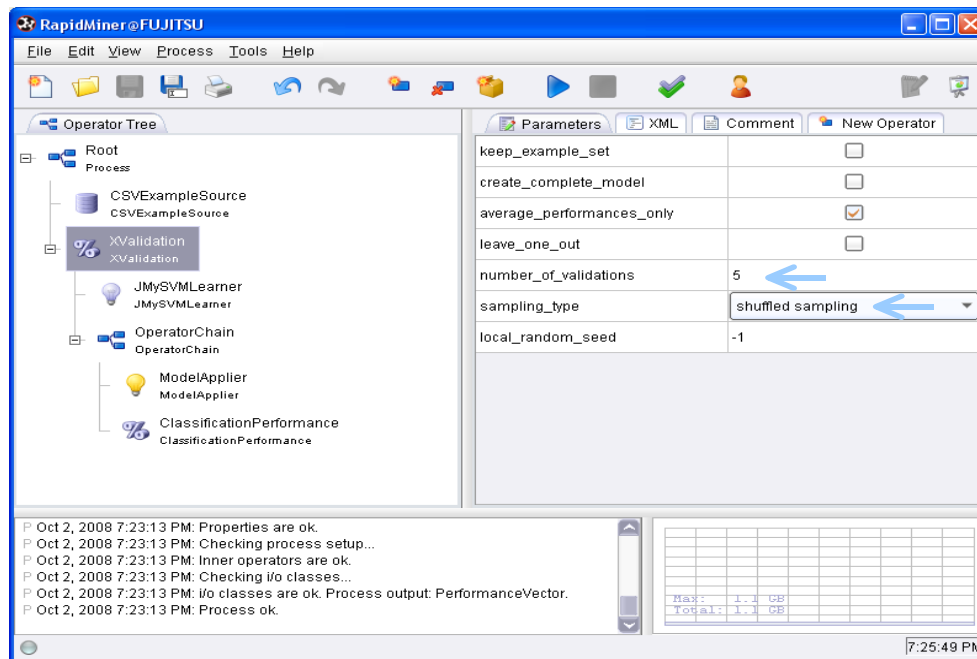

The JMYSVMLEARNER component is a version of Stefan Ruping's MYSVM (<http://www-ai.cs.uni-dortmund.de/SOFTWARE/MYSVM/index.html>). It is available into the menu item NEW OPERATOR / LEARNER / SUPERVISED / FUNCTIONS.

There are many parameters. Their consequence on the results seems not clear. We handle only the complexity parameter ( $C = 1.0$ ) and the kernel type (LINEAR).

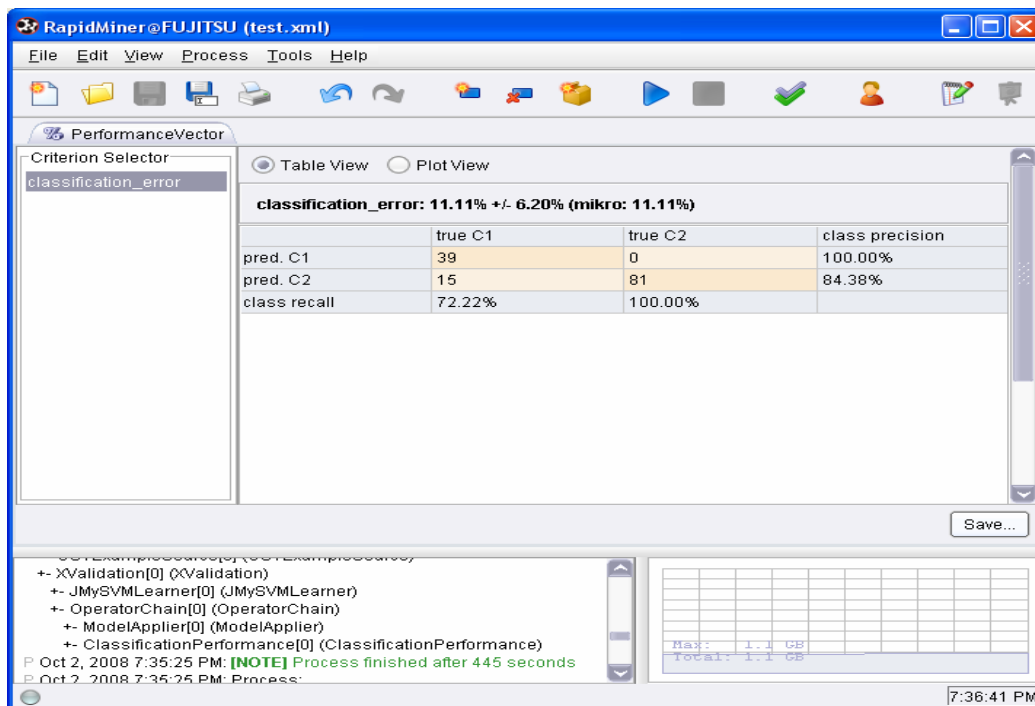

We click on the PLAY button into the toolbar. The computation time is 29 seconds. The memory occupation becomes 338 MB.

We implement a cross validation in order to measure the error rate.

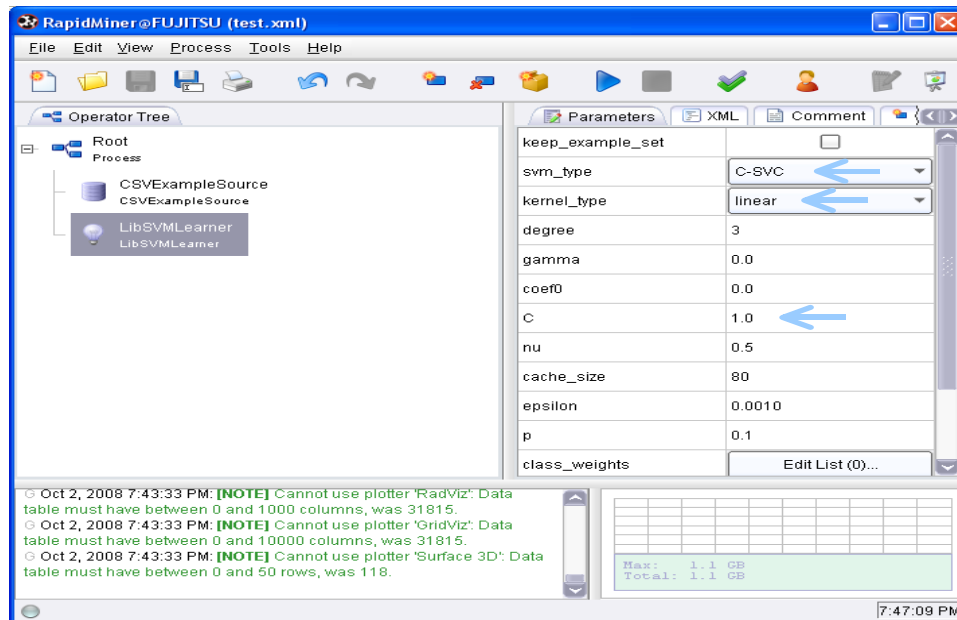

Surprisingly, whereas the structure of RAPIDMINER diagram was very easy to apprehend up to now, the implementation of the cross validation needs complicated handling. Thereafter, we note that the cross validation process corresponds to the repetition of two operations: learning on a part of the dataset, applying and measuring the error rate on the other part of the dataset. We ask `NUMBER_OF_VALIDATIONS = 5` and `SAMPLING_TYPE = SHUFFLED SAMPLING` for the `XVALIDATION` component, we check `CLASSIFICATION_ERROR` for `CLASSIFICATIONPERFORMANCE`.

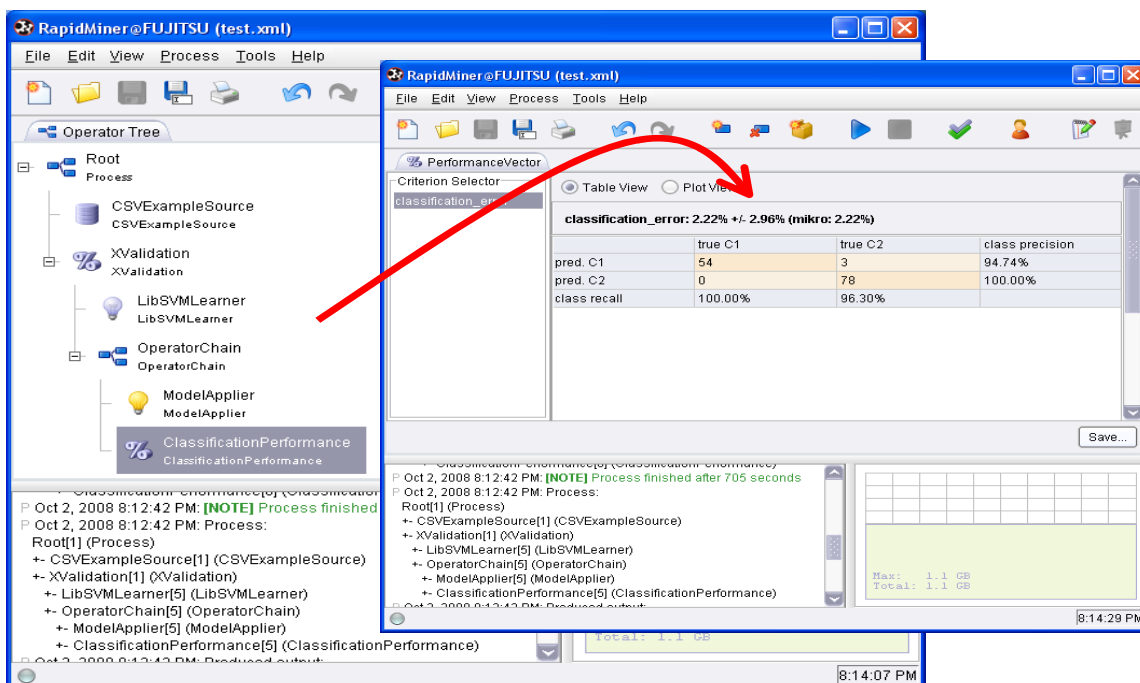

The cross validation error rate is 11% (15 misclassified instances on 135). The computation time is 445 seconds.

### 3.2.2 RAPIDMINER – LIBSVM

A JAVA version of the famous library LIBSVM (<http://www.csie.ntu.edu.tw/~cjlin/libsvm/>) is available into RAPIDMINER. We add the LIBSVMLEARNER component into the diagram. We set the appropriate settings (KERNEL TYPE and C).

The real computation time is 9 seconds. But the listing of the coefficients of the linear classifier takes more time. The memory occupation is 442 MB.

We obtain the cross validation error rate (2%, 3 misclassified instances) with the sequence of components above. Curiously, the computation time is much longer here with 705 seconds. The memory occupation is high: 870 MB.

### 3.3 TANAGRA

TANAGRA is intended to the Windows OS (W95 →Vista). But it can launch on other OS using an emulator or something like that (see <http://data-mining-tutorials.blogspot.com/2009/01/tanagra-under-linux.html> for the utilization of Tanagra under Linux).

First of all, we click on the FILE / NEW menu in order to create a diagram and import the dataset. A dialog box appears, we select the data file.

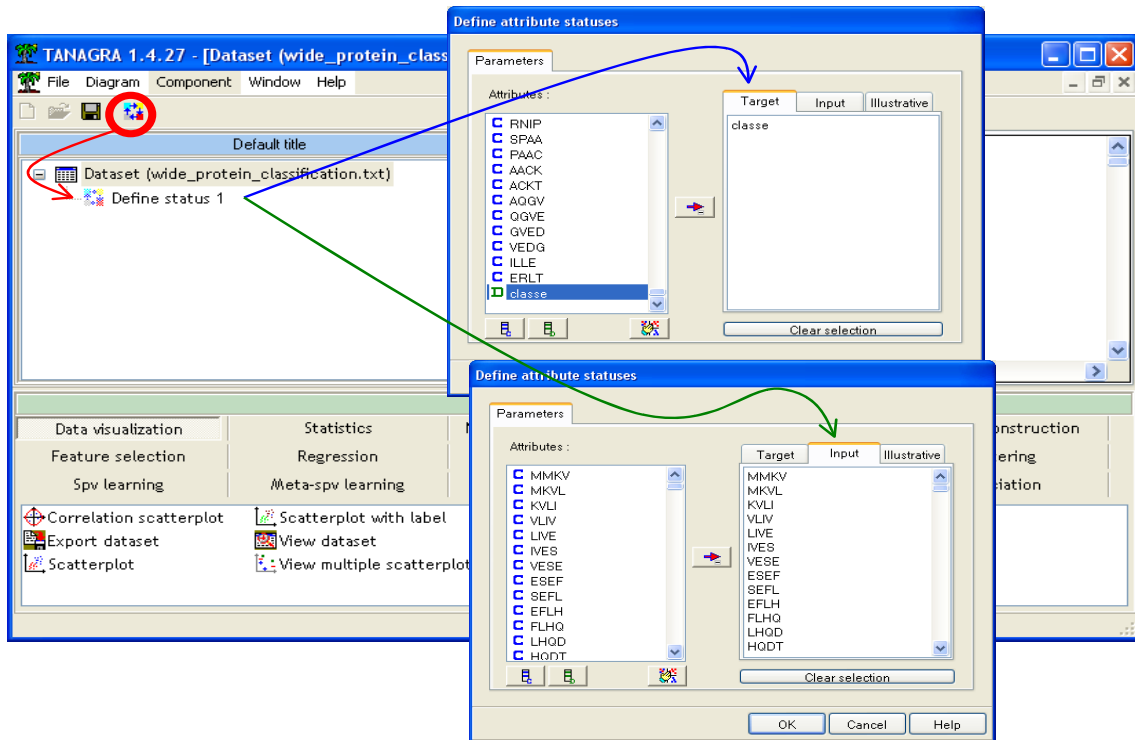

The importation time is 12 seconds. The enumeration of the variables into the visualization window is longer. There are 31810 attributes (1 class attribute + 31809 descriptors) and 135 instances.

Download information	
<b>Datasource processing</b>	
Computation time	12187 ms
Allocated memory	52466 KB
<b>Dataset description</b>	
<b>31810 attribute(s)</b>	
<b>135 example(s)</b>	

We specify the types of the variables using the DEFINE STATUS component. We set CLASSE as TARGET, the other attributes as INPUT.

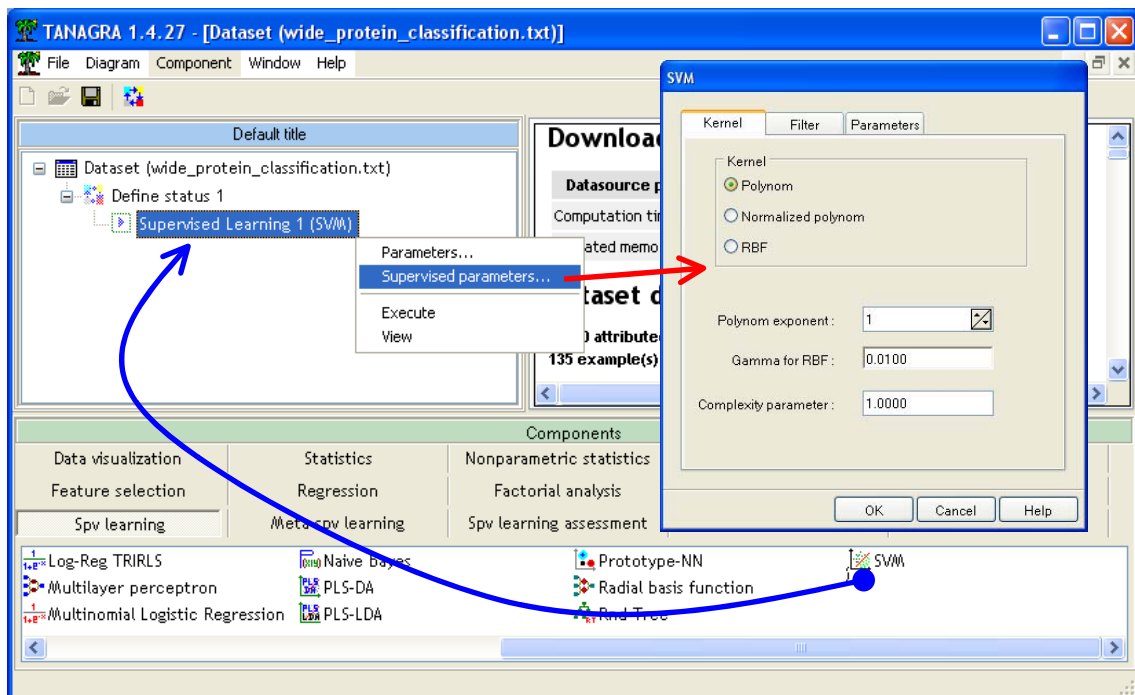

TANAGRA supplies two components for the implementation of SVM.

### 3.3.1 TANAGRA – SVM

The SVM component is a native implementation of the Platt’s SMO algorithm. We add it into the diagram. We click on the PARAMETERS menu in order to set the appropriate settings.

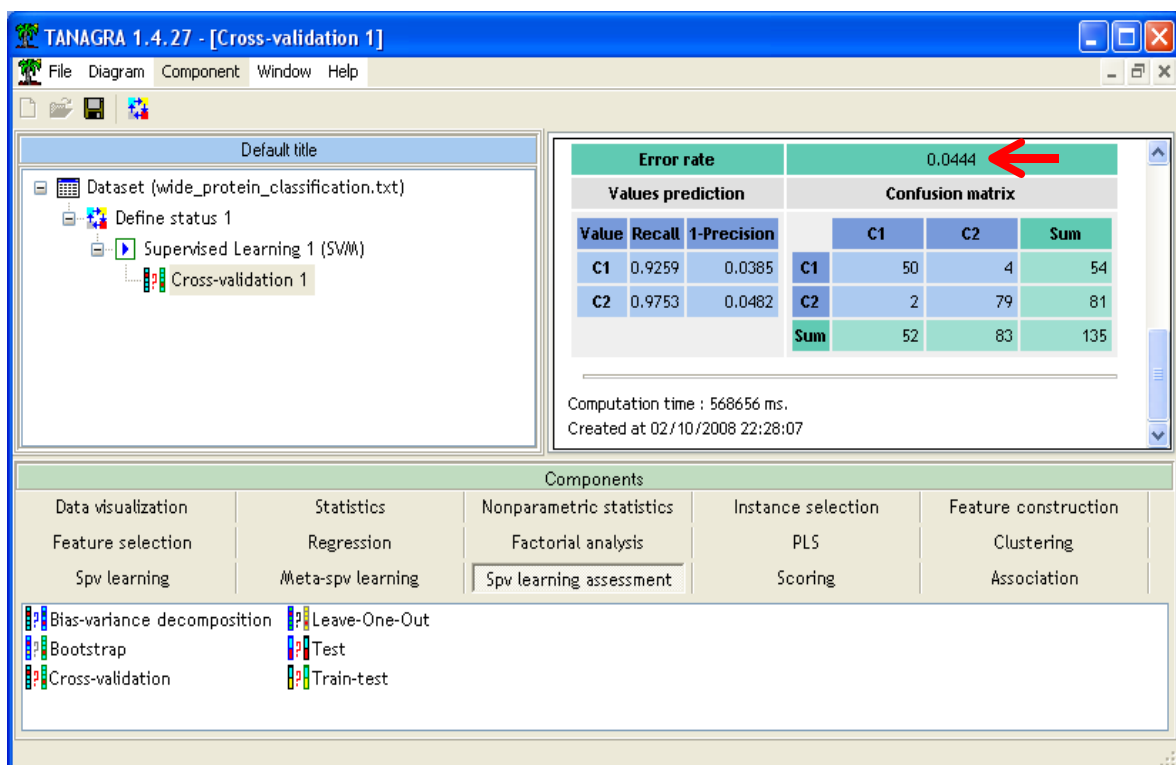

The default settings are suitable. We click on the VIEW menu.

The calculation time is 130 seconds. It is rather high in comparison to other tools. We try to explain why below (Section 3.5). The memory occupation is moderate (393 MB).

Then, we insert the CROSS VALIDATION component (SPV LEARNING ASSESSMENT tab). We activate the PARAMETERS menu.

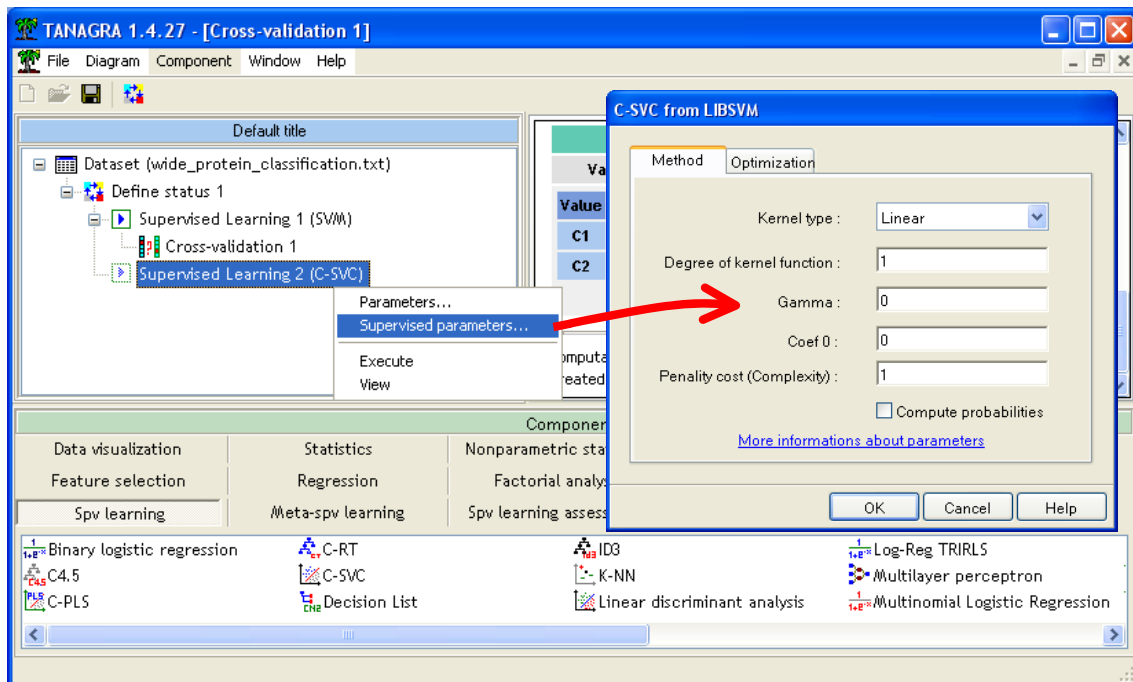

To launch the processing, we click on the VIEW menu. The error rate is 4% (6 misclassified examples). During the calculations, the memory occupation remains stable (393 MB).

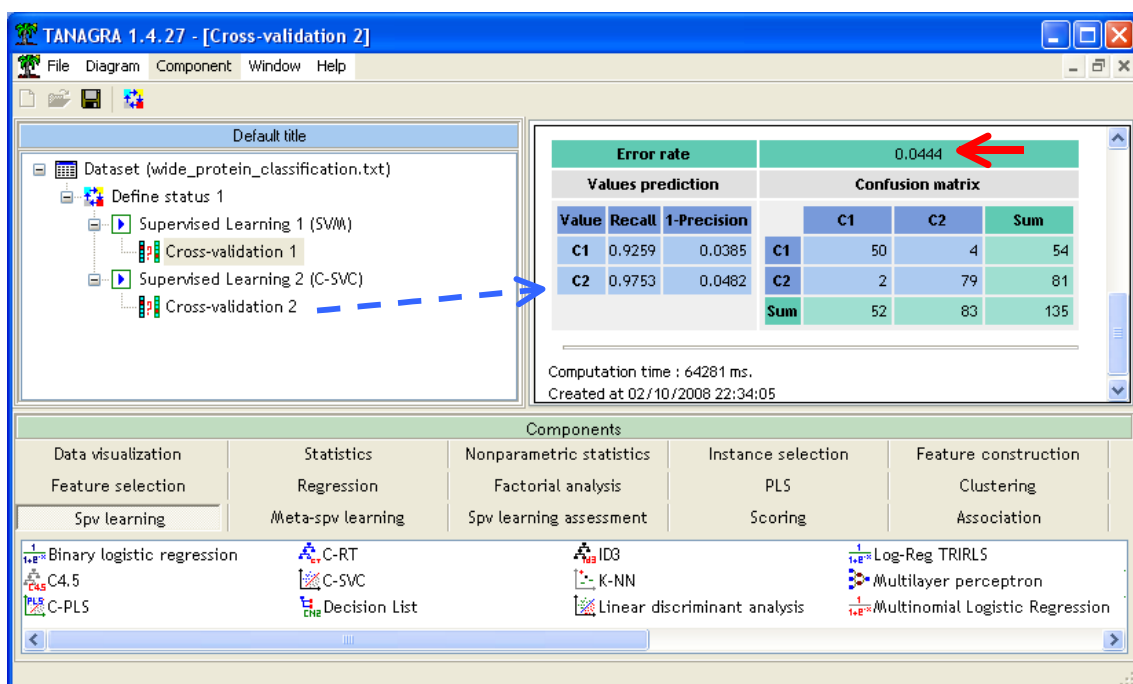

### 3.3.2 TANAGRA – LIBSVM

TANAGRA can use also the LIBSVM library (as DLL – Dynamic Link Library). We add the C-SVC component into the diagram. We click on the PARAMETERS menu. We use the default settings.

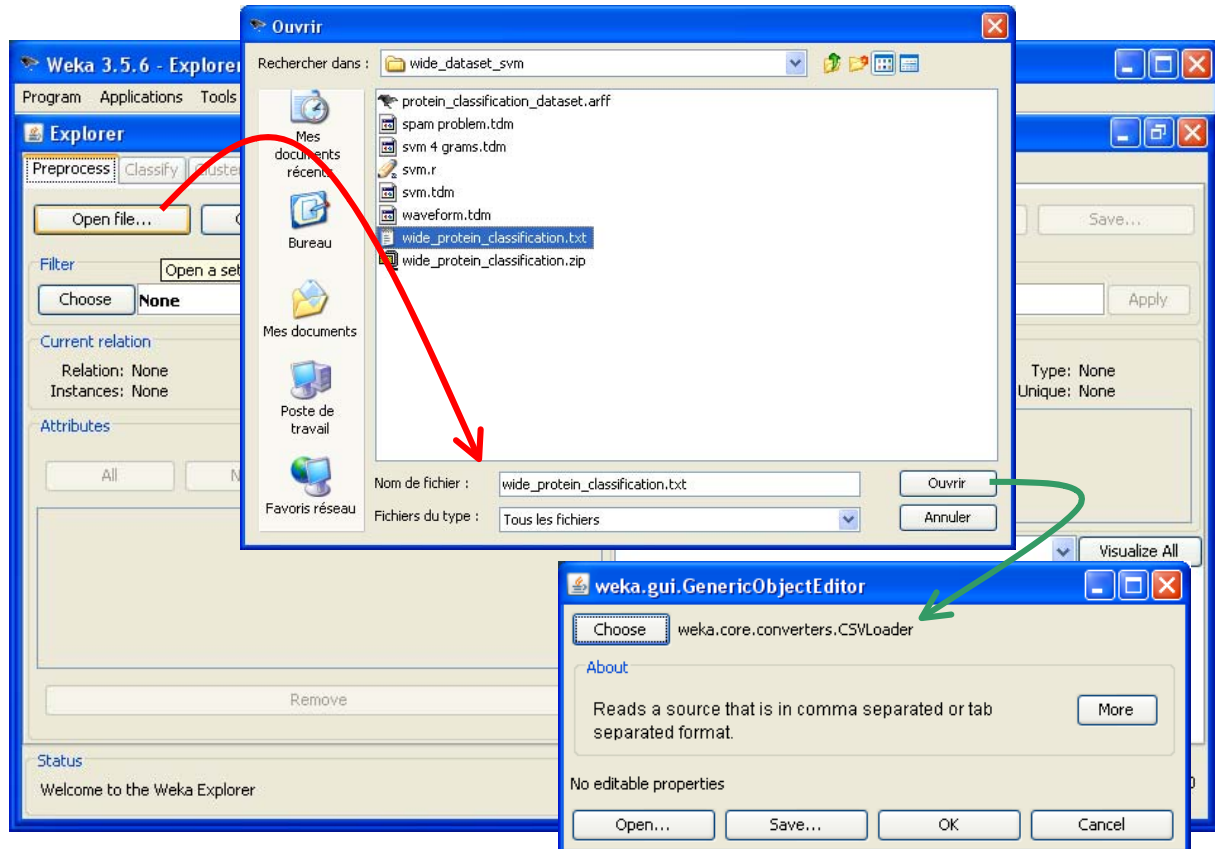

We click on the VIEW menu. The calculation is fast (11 seconds). Even if the dataset is duplicated when we call the library, it seems it is not really detrimental since the memory occupation remains reasonable (406 MB).

We implement the cross validation (5 FOLD). The obtained error rate is 4.44% (6 misclassified instances). The calculation time is 64 seconds; the memory occupation remains stable (406 MB).

### 3.4 WEKA

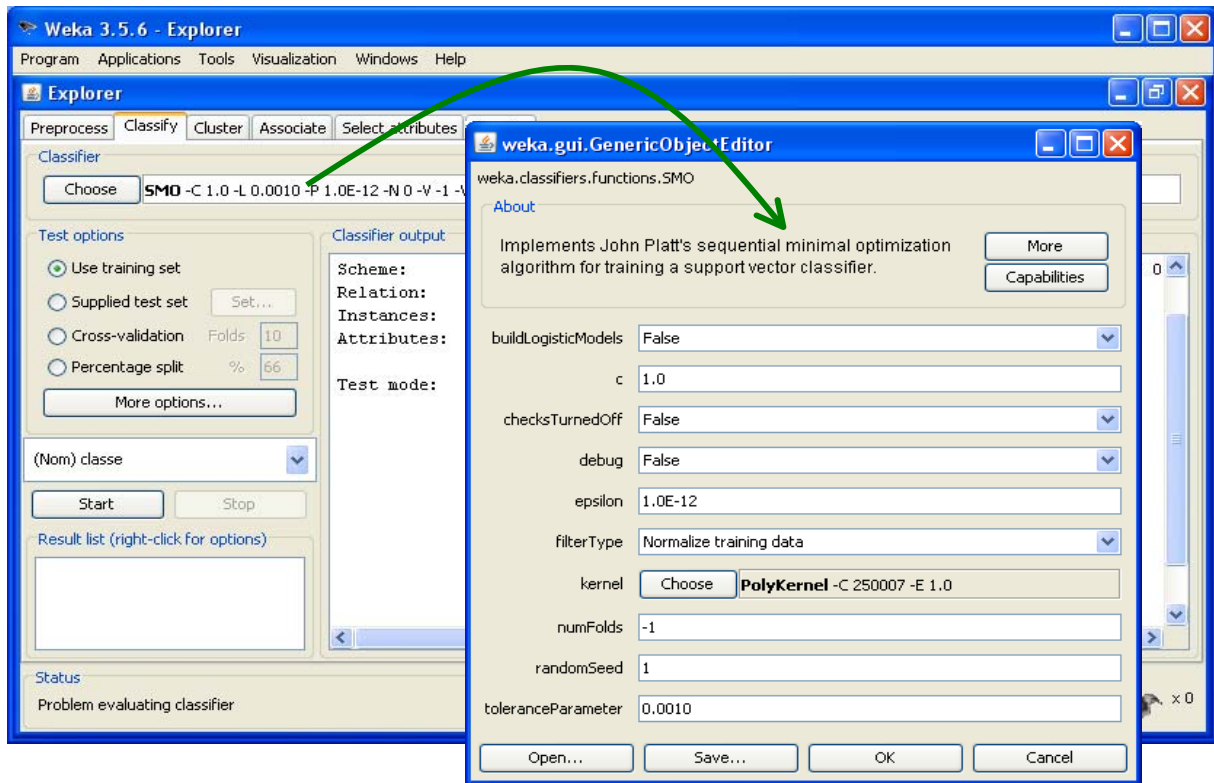

The Java Virtual Machine is automatically launched with WEKA. We use the EXPLORER module in this tutorial. We import the data by clicking on the OPEN FILE button with the CSVLOADER option.

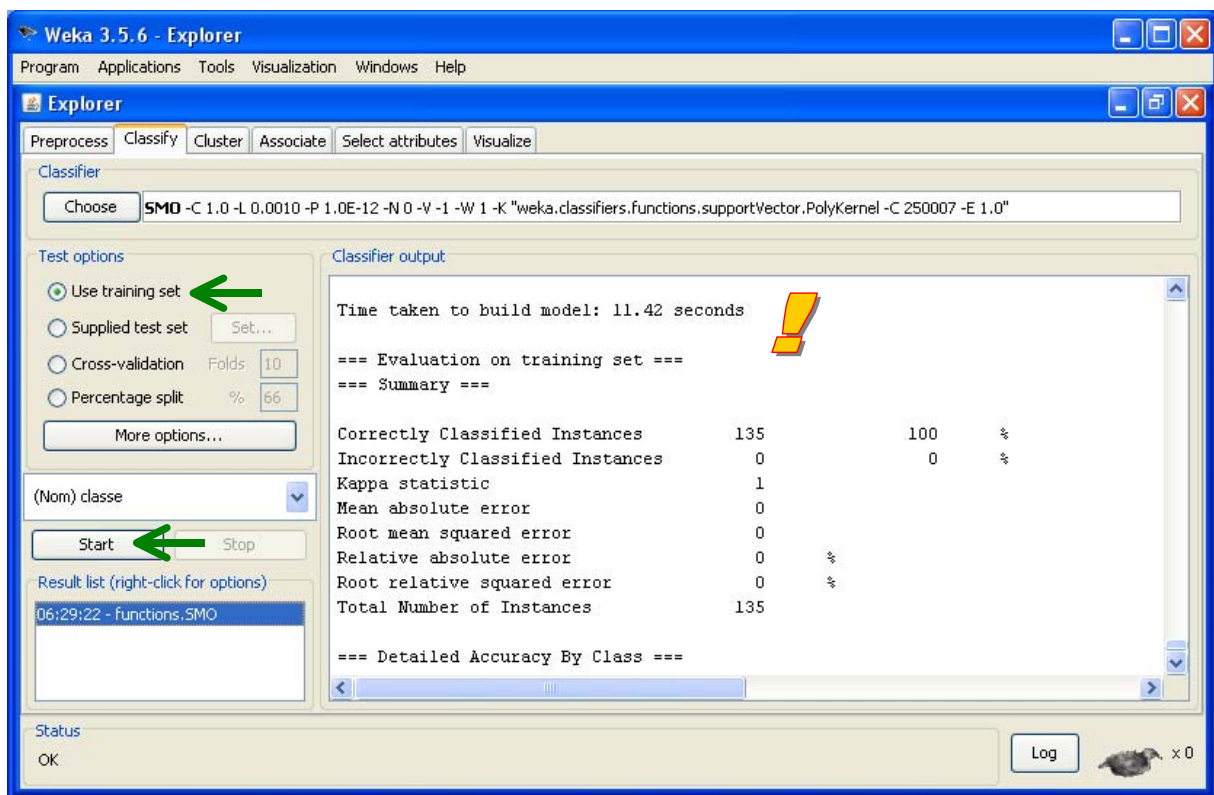

The importation time is fast (10 seconds). The memory occupation reaches to 243 MB.

We activate the CLASSIFY tab. By clicking on the CHOOSE button, we select the SMO algorithm. We can set the appropriate parameters i.e. we set  $C = 1.0$  and a linear kernel (a polynomial kernel with degree = 1).

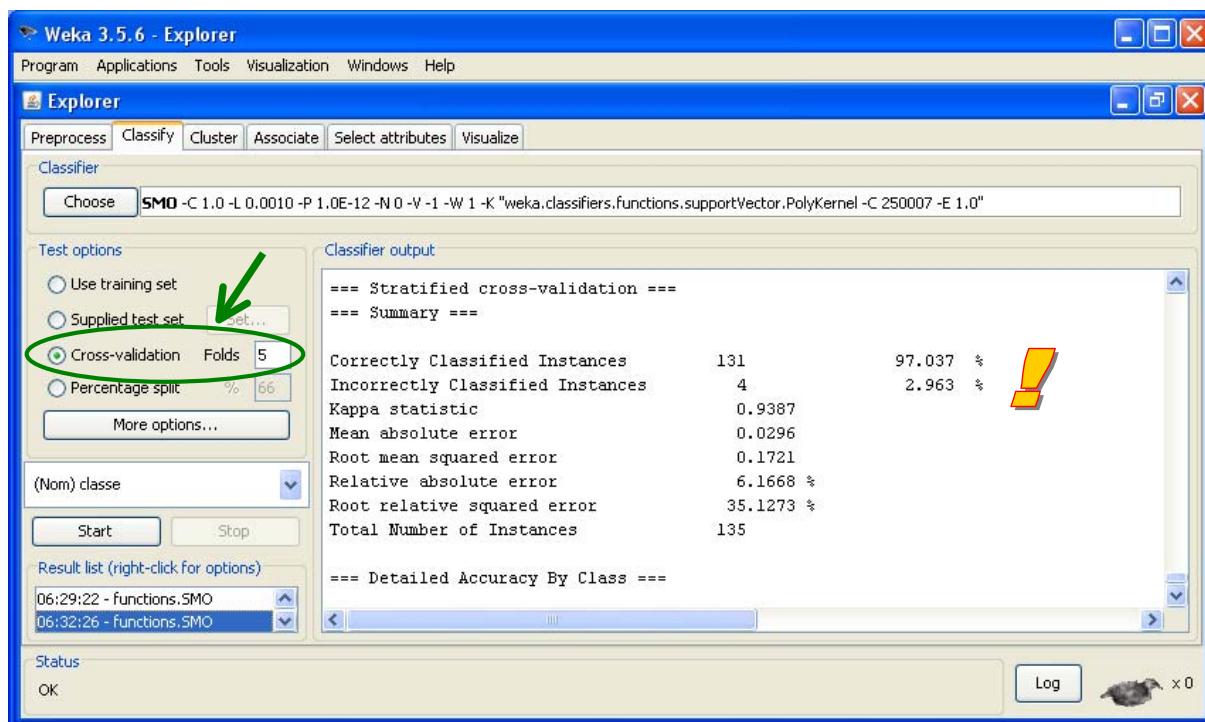

**Note:** The LIBSVM library seems also available into WEKA. But on my computer, I cannot launch the method. It seems the installation failed. The module was not reachable.

First we ask a learning/test session on the same dataset (USE TRAINING SET option). The calculation time is 11 seconds. The resubstitution error rate is 0%.

For the cross validation process, we modify the settings. Then we click again on the START button. The error rate is 3% (4 misclassified instances). The memory occupation reaches 595 MB.

### 3.5 Summary of the main points

Into the table below, we compare the calculation times and the memory occupation of the various versions of SVM.

Tool	Time (sec.)		Cross validation error rate (%)	Memory Occupation (MB)			
	Data Importation	SVM Processing		Launching the tool	After data importation	During the learning process	During the cross validation
ORANGE	95	690	4% (6/135)	25	118	317	406
RAPIDMINER JMySVMLearner	5	29	11% (15/135)	124	210	338	608
RAPIDMINER C-SVC (LIBSVM)	5	9	2% (3/135)	124	210	442	870
TANAGRA - SVM	12	130	4% (6/135)	7	337	393	393
TANAGRA C-SVC (LIBSVM)	12	11	4% (6/135)	7	337	406	406
WEKA - SMO	11	12	3% (4/135)	54	243	489	595

**Error rate.** Although the tools are supposed to use the same method, we note disparities between the performances. The first reason is the organization of the cross validation. The tools does not use the same subdivision for the folds. It is natural that there is a little deviation about the estimated error rate.

The second reason is that the used algorithm is not the same one. That explains the strong disparities in some circumstances. For example, JMYSVMLERARNER seems not efficient compared to the others in the context of our data. It would be necessary to study in detail the algorithm and its settings to understand this failure.

**Processing time.** I think that the LIBSVM library is extraordinary. Whatever tool in which it is integrated, it is very fast. Into Tanagra, the data are duplicated before being sent to the compiled library (DLL), this does not affect the processing time.

SMO of WEKA is also fast. Surprisingly, it is much faster than SMO of Tanagra while the source codes are similar. After a thorough analysis of the stages of the algorithm, it seems that the differences are primarily based on the data structure used. The dataset is organized by row into Weka; they are organized by column into Tanagra. Thus, because SMO algorithm uses intensively a dot product on row vector, Weka is much faster. In other contexts, when the calculations relies mainly on analyzing the data by column (e.g. induction of decision trees), Tanagra is really more efficient (<http://data-mining-tutorials.blogspot.com/2008/11/decision-tree-and-large-dataset.html>).

Morality of this, before you get excited unnecessarily on programming languages and compilers (WEKA → JAVA; TANAGRA → DELPHI), we should first focus on the data structure when we want to work on processing time.

**Memory occupation.** We note again here that JRE (Java Virtual Machine) leads to a more important memory occupation, even if the internal data storage is efficient. We observe this by comparing the memory occupation after the data loading and after the whole processing.

The behavior of RAPIDMINER-LIBSVM during the cross-validation suggests that many intermediate results are kept, leading to unnecessary memory usage.

## 4 Related tools

We tested other tools. They failed at various step of the process. The reasons are not clear sometimes.

- **KNIME (1.5.31 - <http://www.knime.org/>):** It was not possible to import data. During the preview, the software crashes. It seems that this is due to the visualization grid. There is no reason that the internal structures cannot handle the data.
- **R (package e1071 - <http://cran.r-project.org/web/packages/e1071/index.html>):** We use the package "e1071" of R 2.7.2 (<http://www.r-project.org/>). The data file is rightly imported. The loading time is 35 seconds. The memory occupation is grown from 19 MB to 156 MB. The problem occurs when we launch the SVM. R tries to create a vector of 3.8 GB size. It is not possible on my computer. I do not think it is possible under Windows OS. Furthermore, this value (3.8 GB) seems mysterious.

- Many libraries are available online (e.g. [http://www.support-vector-machines.org/SVM\\_soft.html](http://www.support-vector-machines.org/SVM_soft.html)). The main difficulty is to prepare the data in the correct format in order to launch the tool. Some libraries are associated with commercial software such as MATLAB, their diffusion is necessarily limited.

## 5 Conclusion

In drawing a parallel between this tutorial and this one dedicated to the induction of decision trees on large databases (<http://data-mining-tutorials.blogspot.com/2008/11/decision-tree-and-large-dataset.html>), we realize that the solutions are more or less efficient depending on the characteristics of data handled and the learning method used. This confirms the idea that there is no universal solution. We must determine the most appropriate solution depending on the context of the study that we conducted.

Anyone can reproduce the experiment described in this tutorial. We can also lead the experiment on a dataset with other characteristics (e.g. many rows, few columns). The conclusions can be different in this context.
